Cronbach's Alpha Calculation	4
Lineplot – Descriptive Statistics	8
Repeated Measures GLM	9

Introduction

The American Panel Study (data accessible here: https://wc.wustl.edu/taps-data-archive) contains the Moral Foundations Questionnaire in its 20-item version. This was administered to the panel in March of 2012, during Eave 10 of the sutdy. Here, I will use the 20-item questionnaire to create an analysis that replicates the work of Graham, Haidt and Nosek for the Moral Relevance subscale.

Before I begin, I load in the data (available for download here) and relevant packages.

```
# Load in data
taps = read.csv("~/Desktop/Working/Moral-Psychology/TAPS10/taps10MFQ.csv",
    header = TRUE)

# Libraries
library(car)
library(dplyr)
library(gsplot2)
library(ggplot2)
library("ggpubr")
library("reshape2")
library(scales)
library(lme4)
library(lsr)
```

Clean Data

In this section, I organize the variables that I will need for the graph and the linear model.

First, I remove participants who did not pass the manipulation check items.

```
#### Remove Distractor Items ###
table(taps$attchecka)
##
##
         2
             3
                  4
                      5
## 812 372 219 165 83
taps <- taps[!(taps$attchecka == "4"), ]
taps <- taps[!(taps$attchecka == "5"), ]</pre>
table(taps$attcheckb)
##
##
      1
           2
                 3
                      4
                           5
                                 6
##
     27
                17
                     54
                        160 1117
taps <- taps[!(taps$attcheckb == "1"), ]</pre>
taps <- taps[!(taps$attcheckb == "2"), ]
taps <- taps[!(taps$attcheckb == "3"), ]</pre>
```

Next, I create variables that represent aggregate scores on each of the moral foundations based on the Moral Relevance subscale.

```
### Harm ###
taps$emote <- taps$emote - 1
taps$weak <- taps$weak - 1
taps$Harm <- rowMeans(taps[, c("emote", "weak")], na.rm = TRUE)

### Fairness ###
taps$treatd <- taps$treatd - 1
taps$unfair <- taps$unfair - 1
taps$Fairness <- rowMeans(taps[, c("treatd", "unfair")], na.rm = TRUE)

### Ingroup ###
taps$lovec <- taps$lovec - 1
taps$betray <- taps$betray - 1
taps$Ingroup <- rowMeans(taps[, c("lovec", "betray")], na.rm = TRUE)

### Authority ###
taps$auth <- taps$auth - 1</pre>
```

```
taps$conform <- taps$conform - 1
taps$Authority <- rowMeans(taps[, c("auth", "conform")], na.rm = TRUE)

### Purity ###
taps$purity <- taps$purity - 1
taps$purity <- taps$purity - 1
taps$Purity <- rowMeans(taps[, c("purity", "disgust")], na.rm = TRUE)</pre>
```

```
For the descriptive statistics line plot that I will create later, I recode a political ideology
variable to reflect factor labels rather than numeric.
table(taps$ideo7)
##
##
         2
              3
                      5
## 88 208 176 274 173 253 79
# 1 = Very Liberal, 7 = very conservative

Lineplot – Descriptive Statistics

In this section, I will create a linegraph that displays the average score on each foundation as a function of the respondent's political ideology. To do this, I generate average scores by moral foundation.

```
Harm <- aggregate(Harm ~ ideology, taps, mean, na.rm = TRUE)
Fairness <- aggregate(Fairness ~ ideology, taps, mean, na.rm = TRUE)
Ingroup <- aggregate(Ingroup ~ ideology, taps, mean, na.rm = TRUE)
Authority <- aggregate(Authority ~ ideology, taps, mean, na.rm = TRUE)
Purity <- aggregate(Purity ~ ideology, taps, mean, na.rm = TRUE)</pre>
```

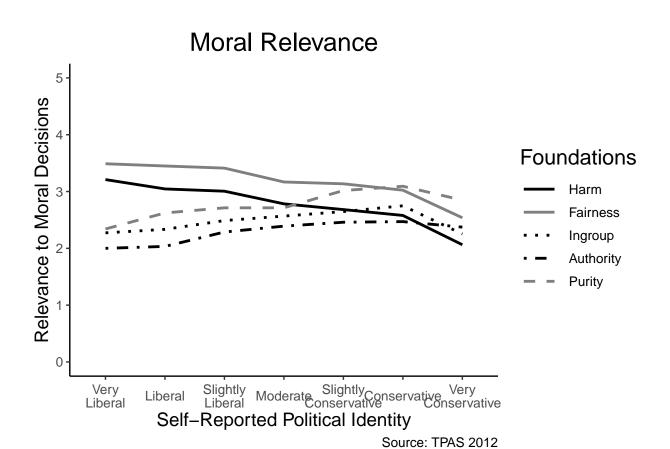

In order for ggplot to graph the data, the points need to be merged into one large data frame and reshaped into the proper data frame formation. I do this with the code below.

```
moral <- merge(Harm, Fairness, by.x = "ideology", by.y = "ideology",
    all.x = TRUE, all.y = TRUE)
moral <- merge(moral, Ingroup, by.x = "ideology", by.y = "ideology",
    all.x = TRUE, all.y = TRUE)
moral <- merge(moral, Authority, by.x = "ideology", by.y = "ideology",
    all.x = TRUE, all.y = TRUE)
moral <- merge(moral, Purity, by.x = "ideology", by.y = "ideology",
    all.x = TRUE, all.y = TRUE)

mfq <- reshape2::melt(moral, id.var = "ideology")</pre>
```

Now, I create the graph

```
ggplot(mfq, aes(x = ideology, y = value, group = variable)) +
    geom_line(aes(linetype = variable, color = variable), size = 1) +
    theme_classic() + scale_linetype_manual("Foundations", breaks = c("Harm",
    "Fairness", "Ingroup", "Authority", "Purity"), values = c(Harm = "solid",
    Fairness = "solid", Ingroup = "dotted", Authority = "dotdash",
    Purity = "dashed")) + scale_color_manual("Foundations", breaks = c("Harm",
    "Fairness", "Ingroup", "Authority", "Purity"), values = c(Harm = "black",
    Fairness = "grey50", Ingroup = "black", Authority = "black",
    Purity = "grey50")) + ggtitle("Moral Relevance") + xlab("Self-Reported Political Ide
    ylab("Relevance to Moral Decisions") + ylim(0, 5) + labs(caption = "Source: TPAS 201
    theme(text = element_text(size = 12, colour = "black"), axis.title = element_text(s
        colour = "black"), title = element_text(size = 16, colour = "black"),
       plot.caption = element_text(size = 10, color = "black"),
       axis.text.x = element_text(angle = 0, hjust = 0.5, vjust = 0.5),
       plot.title = element_text(hjust = 0.5), legend.key.width = unit(2,
            "line")) + scale_x_discrete(labels = wrap_format(10))
```

Repeated Measures GLM

To see if liberals and conservatives differ significantly on the individualizing versus binding foundations, the authors generated a repeated measures GLM to capture the relationship. Additionally, they tested to see if the relationship would be moderated by politics.

Here, I replicate the model using the TAPS dataset.

I generate a composite score for the individualizing and binding foundations.

Next, I generate a difference score between the individualizing and binding foundations.

```
taps$diffscore <- taps$indiv - taps$bind
```

Now, I run the model and print out a table summarizing the results and include an η^2 statistic.

```
diff.model <- lm(diffscore ~ ideo7, data = taps)</pre>
summary(diff.model)
##
## Call:
## lm(formula = diffscore ~ ideo7, data = taps)
##
## Residuals:
##
        Min
                       Median
                                    30
                  10
                                            Max
## -2.67649 -0.52571 -0.01581
                              0.49017 2.70241
##
## Coefficients:
##
               Estimate Std. Error t value Pr(>|t|)
## (Intercept) 1.35514
                                     23.42
                           0.05787
                                             <2e-16 ***
               -0.22422
                           0.01316 -17.04
                                             <2e-16 ***
## ideo7
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
## Residual standard error: 0.7997 on 1249 degrees of freedom
     (1141 observations deleted due to missingness)
## Multiple R-squared: 0.1886, Adjusted R-squared: 0.188
## F-statistic: 290.3 on 1 and 1249 DF, p-value: < 2.2e-16
etaSquared(diff.model)
##
            eta.sq eta.sq.part
```

ideo7 0.1886143 0.1886143

The results are interpreted as follows:

The F-statistic: 288.7 on 1 and 1249 DF, p-value: < 2.2e-16 reflects the moderation of politics in the model. To find the difference between the scales as is, we square the t-value next to the (Intercept) row and use that p-value

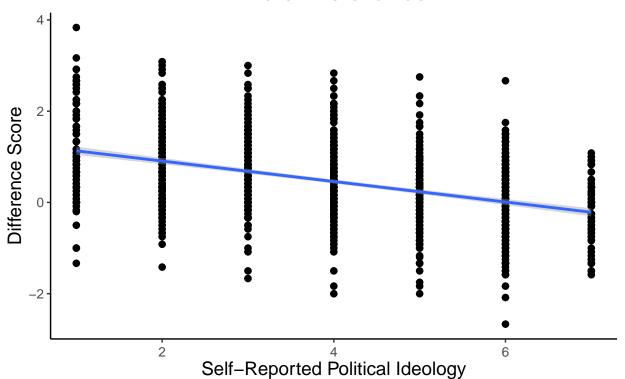

The results are as follows:

- Aggregate difference between individualizing and binding foundations: F(1, 1249) = 546.1569, p < .001
- Moderation by politics: F(1, 1249) = 288.7, p < .001, $\eta^2 = .188$

To see the distribution of the scores, I generate a scatterplot with the linear model fitted. the political ideology variable is acress the x-axis and it is represented by 1 = Very Liberal to 7 = Very Conservative

```
# Fit plot with linear regression line
ggplot(taps, aes(x = ideo7, y = diffscore)) + geom_point(size = 2) +
    geom_smooth(method = "lm", se = TRUE, fullrange = FALSE,
    level = 0.95) + theme_classic() + ggtitle("Moral Relevance") +
```

Moral Relevance
